Advance Python Assignment

Topic-4: Reading and Writing Files

Q1. Explain reading from a file in Python.

Ans.
Reading from a file in Python is used to access stored data from a file. It is an important part of file handling. Python provides functions like read(), readline(), and readlines() to read file content. The read() function is used to read the entire file, readline() reads one line at a time, and readlines() reads all lines into a list. These functions help in processing and displaying file data easily. Reading from files is useful when we want to use previously stored information in our programs.

Example:
```
file = open("data.txt", "r")
content = file.read()
print(content)
file.close()
```

Q2. Explain writing data into a file in Python.

Ans.
Writing data into a file in Python is done using write() and writelines() functions. These functions are used to store data in a file. When a file is opened in 'w' mode, it creates a new file or overwrites the existing content. In 'a' mode, it adds new data to the end of the file. Writing into files is useful for saving outputs, reports, and user data. It helps in storing information for future use and makes programs more useful.

Example:
```
file = open("result.txt", "w")
file.write("This is writing example")
file.close()
```
