Advance Python Assignment

Topic-1: Printing on Screen

Q1. Introduction to the print() function in Python.

Ans.
The print() function in Python is used to display output on the screen. It is one of the most basic functions and is widely used in programming. With the help of print(), we can show text, numbers, and variable values to the user. It helps in understanding program results and debugging code. The function can print multiple values at the same time and improves the readability of output. It is very useful for beginners as well as professionals while working with Python programs.

Example:
```
print("Hello, World!")
```

Q2. Formatting outputs using f-strings and format() in Python.

Ans.
In Python, output can be formatted using f-strings and the format() method. These methods are used to combine text and variables in a clean and readable way. F-strings are simple and commonly used, where variables are written inside curly braces. The format() method is another way to insert values into a string. Both methods help in creating better and more understandable output. They are useful when we want to display dynamic values in a structured format.

Example:
```
name = "Anshu"
age = 20

print(f"My name is {name} and I am {age} years old.")
print("My name is {} and I am {} years old.".format(name, age))
```
